Review: Data Structures: Binary search trees

- When adding or looking for items, move left if the new item is smaller, right if bigger than the current vertex.
- If a tree of N items is balanced, takes about log₂ N comparisons to test if an item is present.
- Can be used to sort items.
- E.g. build a tree with: 55, 62, 37, 49, 71, 14, 17

Analysis of Algorithms

9 September 2021

Overview

• Motivating example.

• Mathematical concepts: big-O, little-o, big- Θ .

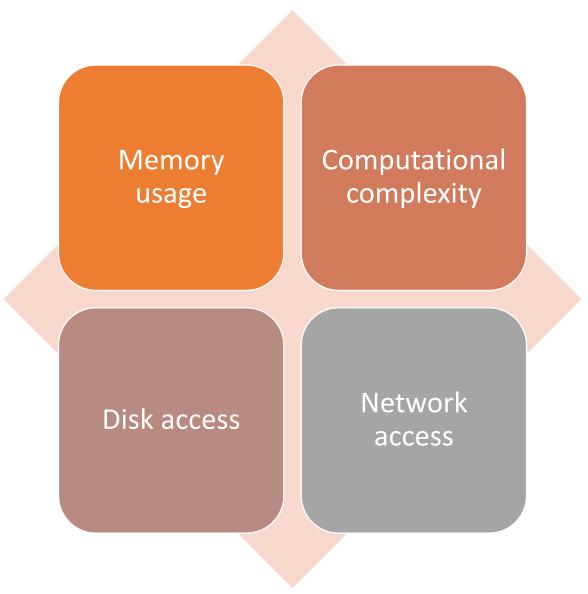

• Examples.

Motivating example: finding a patient

• How much work is it to find a specific patient: Rodriguez, Kathy

- If I have *n* total patients stored as:
 - an unsorted list?
 - a list sorted by name?
 - a binary search tree sorted by name?
 - a dictionary keyed by name?

Performance considerations

Mathematical Review

Big O, Little o, and Big Θ

Big O

For a given f(x), we say

$$f(x) = O(g(x))$$

if and only if there exists x_0 and M such that

$$|f(x)| \le Mg(x)$$

for all $x \ge x_0$.

$$3x^5 + 200x^4 + 7 = O(x^5)$$

$$3x^5 + 200x^4 + 7 = O(x^5)$$

Proof:

For $x \ge 201$,

$$x^5 = x \cdot x^4 \ge 201x^4 = 200x^4 + x^4 \ge 200x^4 + 201^4 > 200x^4 + 7$$

Therefore for $x \ge 201$,

$$4x^5 = 3x^5 + x^5 > 3x^5 + 200x^4 + 7 = |3x^5 + 200x^4 + 7|$$

That is, $|3x^5 + 200x^4 + 7| < Mx^5$ for all $x \ge x_0$ where M = 4 and $x_0 = 201$. The claim follows immediately, by definition of "Big O".

Lemma

If

$$f(x) = \sum_{i=0}^{m} a_i x^i = a_0 + a_1 x + \dots + a_m x^m$$

then

$$f(x) = O(x^m)$$

That is, a polynomial of degree m is $O(x^m)$.

Warning

• The "=" symbol in Big O notation is a symbol denoting a non-symmetric relationship; it is not equality.

• For this reason, sometimes people prefer to write

$$f(x) \in O(g(x))$$

Little o

For a given f(x), we say

$$f(x) = o(g(x))$$

if and only if for every $\varepsilon > 0$, there exists N such that

$$|f(x)| \le \varepsilon g(x)$$

for all $x \ge N$.

$$2x = o(x^2)$$

$$2x = o(x^2)$$

Proof:

Let $\varepsilon > 0$ be given. Define $N = \frac{2}{\varepsilon}$.

Then for any $x \ge N$, (multiplying both sides by x)

$$x^2 \ge \frac{2}{\varepsilon} x$$

SO

$$\varepsilon x^2 \ge 2x = |2x|$$

where the last equality holds because $\varepsilon > 0$ implies N > 0 and thus $x \ge N > 0$.

Lemma

If

$$f(x) = o(g(x))$$

then

$$f(x) = O(g(x)).$$

The converse does not hold.

Big Θ

For a given f(x), we say

$$f(x) = \Theta(g(x))$$

if and only if there exists x_0 , M_1 and M_2 such that

$$M_1 g(x) \le |f(x)| \le M_2 g(x)$$

for all $x \ge x_0$.

smaller

 $O(\log \log n)$

 $O(\log n)$

0(1)

 $O(n^a), 0 < a < 1$

O(n)

 $O(n \log n)$

 $O(n^a), a > 1$

 $O(a^n), a > 1$

O(n!)

larger

Back to informatics

In data science and informatics...

... we usually want to quantify memory usage and computational complexity in terms of the number of data points, n.

If we have n glucose readings, what is the memory usage and compute time of the following algorithm, in terms of Big Θ ?

```
max_glucose = 0
for glucose in patients_glucose:
   if glucose > max_glucose:
        max_glucose = glucose
```

How long will this take to run in the big O sense? Assume data is a Python list of length n.

```
total = 0
for i in range(100):
    for j in range(i, 100):
        total += i * j * len(data)
```

If we have n nmers all of length 15, what is the memory usage and compute time of the following algorithm, in terms of Big O?

```
for nmer in nmers:
    hashed_values = [
        (((int(sha256(nmer.lower().encode()).hexdigest(), 16)
        % bits_48) * a) % p) & scale
        for a in range(100)
    ]
```

If we have n nmers all of length 15, what is the memory usage and compute time of the following algorithm, in terms of Big O?

Observation

- You can reduce runtime significantly for specific datasets without changing the Big O, little o, or Big Θ .
- If the size of your data can change, then reducing the Big O, little o, or Big Θ is more important.
 - Speedups for fixed-size datasets will come "for free" with improvements in computer technology.

If we have n glucose readings, what is the memory usage and compute time of the following algorithm, in terms of Big O?

```
distinct_readings = []
for glucose in patients_glucose:
    for old_value in distinct_readings:
        if glucose == old_value:
            break
    else:
        distinct_readings.append(glucose)
```

If we have n glucose readings, what is the memory usage and compute time of the following algorithm, in terms of Big O?

```
distinct_readings = set()
for glucose in patients_glucose:
    distinct_readings.add(glucose)
distinct_readings = list(distinct_readings)
```

Timing

Recall:

time.time()

Returns the time in seconds since the beginning of the Unix epoch (Jan 1, 1970 00:00 GMT).

We can thus subtract times at the beginning and end to calculate runtime.

```
$ python bubblesort.py
Runtime: 10.022397994995117 s
$ python bubblesort.py
Runtime: 9.96274995803833 s
$ python bubblesort.py
```

Runtime: 10.286312341690063 s

```
# ensure consistent random numbers

      + p9.scale_x_log10()
      + p9.scale_y_log10()
```

Example: merge sort

```
def merge sort(data):
  if len(data) <= 1:</pre>
    return data
  else:
    split = len(data) // 2
    left = iter(merge_sort(data[:split]))
    right = iter(merge_sort(data[split:]))
    result = []
    # note: this takes the top items off the left and right piles
    left top = next(left)
    right_top = next(right)
    while True:
      if left top < right top:</pre>
        result.append(left top)
        try:
          left top = next(left)
        except StopIteration:
          # nothing remains on the left; add the right + return
          return result + [right_top] + list(right)
      else:
        result.append(right_top)
        try:
          right top = next(right)
        except StopIteration:
          # nothing remains on the right; add the left + return
          return result + [left_top] + list(left)
```

```
import plotnine as p9
import pandas as pd
                                                                       Comparison of
sizes = [2 ** i for i in range(14)]

1e3

le1

Python operations

- Looking up or setting an item in a list or dictionary by index.
 - *0*(1)
 - For dictionaries, this is assuming the add doesn't require reallocating storage.
- Checking if an item is in a list
 - O(n)
- Checking if an item is in a set
 - *0*(1)

Computational Complexity of Common Informatics Tasks

- Comparison sort
 - $O(n \log n)$
- Binary tree insertion/searching/deletion
 - Arbitrary tree: O(n)
 - Balanced tree: $O(\log n)$
- Matrix multiplication
 - Usual algorithm: $O(n^3)$
 - Strassen algorithm: $O(n^{2.807355})$
 - Coppersmith-Winograd: $O(n^{2.375477})$

Computational Complexity of Common Informatics Tasks

- Traveling salesman problem
 - Via dynamic programming: $2^{O(n)}$
 - Brute force: O(n!)
- PCA, *n* data points, *p* features
 - $O(\min(p^3, n^3))$
- Fast Fourier transform (time series analysis)
 - $O(n \log n)$
- Naïve k-nearest neighbors (with p features)
 - O(np + kn) or O(knp) depending on implementation
- Lloyd's algorithm (k-means; p features; i iterations)
 - O(nkpi) but for convergence $i = 2^{\Omega(\sqrt{n})}$
